You wanted to cook a new dish

After a lot of trial and error, you made your first version of dish

You want to improvise your dish

So you add few other ingredients and make a 2nd version of your dish

Recipe 1.2

Add Chicken

Everything is messed up

Wouldn't it be great if there was a **time machine** which stores all your recipes and dishes seperately so if something goes wrong you could go back to the previous dish

*I guess my 1st
recipe was perfect*

You are still not satisfied

So you again improvise your recipe and make a new 3rd version of your dish

Recipe 1.3

Add Donuts

Earlier Developer would have their Backup source code in seperate folders. Reverting back and collaborating is a tedious job

That is where GIT comes into play

Git is a **distributed version control system**

Git **tracks the changes** you made, so you have a record of what has been done, and you can revert to specific versions. It makes collaboration easier, allowing changes by multiple people to all be merged into one source

And what if you have a team
and everyone wanted to taste each version
of your dish and add their own ingredients
and contribute to your masterpiece

Git can automatically merge the changes, so two people can even work on different parts of the same file and later merge those changes without losing each other's work!
